

# Assignment 03 Solutions

## 1. What is the concept of an abstract superclass?

**Ans:** An abstract class/superclass can be considered as a blueprint for other classes. It allows you to create a set of methods that must be created within any child classes built from the abstract class. A class which contains one or more abstract methods is called an abstract class.

Whereas an abstract method is a method that has a declaration but does not have an implementation

```
In [1]: from abc import ABC, abstractmethod
class Polygon(ABC): # Abstract Class
    @abstractmethod
    def noofsides(self): # Abstract Method
        pass
class Triangle(Polygon):
    def noofsides(self): # overriding abstract method in child class Triangle
        print("I have 3 sides")
class Pentagon(Polygon):
    def noofsides(self): # overriding abstract method in child class Pentagon
        print("I have 5 sides")
```

## 2. What happens when a class statement's top level contains a basic assignment statement?

**Ans:** When a Class statement's top level contains a basic assignment statement, its usually treated as a class attribute or class level variable.

where as assignment statements inside methods are treated as instance attributes or local attributes.

When an instance of a class is created a single copy of class attributes is maintained and shared to all instances of class. where as each instance object maintains its own copy of instance variables.

```
In [2]: class Person:
    species = 'Homesapiens' # class attribute
    def __init__(self,name,gender):
        self.name = name # instance attributes
        self.gender = gender
```

## 3. Why does a class need to manually call a superclass's init method?

```
In [3]: class Person:
        def __init__(self, name, age):
            self.name = name
            self.age = age
        class Employee(Person):
            def __init__(self, name, age, salary):
                super().__init__(name, age)
                self.salary = salary
emp_1 = Employee('Vivek', 28, 20000)
print(emp_1.__dict__)

{'name': 'Vivek', 'age': 28, 'salary': 20000}
```

#### 4. How can you augment, instead of completely replacing, an inherited method?

**Ans:** `super()` method can be used to augment, instead of completely replacing, an inherited method.

```
In [4]: class Person:
        def __init__(self, name, gender):
            self.name = name
            self.gender = gender
        class Employee(Person):
            def __init__(self, name, gender, salary):
                super().__init__(name, gender)
                self.salary = salary
emp_1 = Employee('Vivek', 'Male', 10000)
print(emp_1.__dict__)

{'name': 'Vivek', 'gender': 'Male', 'salary': 10000}
```

#### 5. How is the local scope of a class different from that of a function?

**Ans:** A Variable which is defined inside a function is local to that function. it is accesible from the point at which it is defined until the end of the function, and exists for as long as the function is existing.

Similary a variable inside of a class also has a local variable scope. Variables which are defined in the class body (but outside all methods) are called as class level variables or class attributes. they can be referenced by there bare names within the same scope, but they can also be accessed from outside this scope if we use the attribute access operator `(.)` on a class or an instance of the class.

```
In [5]: def hello(name):  
        name = name  
        print(f'you\'re name is {name}')  
hello('Mano Vishnu')  
try:  
    name  
except NameError:  
    print('Name variable is not available outside hello function scope')  
  
class Person:  
    species = "HomeSapines"  
    def __init__(self):  
        pass  
print(Person.species) # Accessing species using class name  
Male = Person()  
print(Male.species) # Accessing species using instance of class
```

you're name is Mano Vishnu

Name variable is not available outside hello function scope

HomeSapines

HomeSapines
